Abstract—Feedback linearization allows for the local transformation of a nonlinear system to an equivalent linear one by means of a coordinate transformation and a feedback law. Feedback linearization of large-scale nonlinear network systems is typically difficult, since existing conditions become harder to check as the network size becomes larger. In this letter, we provide novel conditions to test whether a nonlinear network is feedback-linearizable. Specifically, given some dedicated control inputs injected to a set of network nodes, we derive an easy-to-check algebraic condition that can be tested on the Jacobian matrix of the network dynamics evaluated at some desired working point. Furthermore, our requirements are sufficient for (local) controllability, and thus provide a testable condition for controllability of large-scale nonlinear networks. Finally, we validate our findings by enforcing the formation of desired synchronization patterns in networks of coupled oscillators.

Index Terms—Control of networks, feedback linearization, algebraic/geometric methods.

I. INTRODUCTION

The ability to effectively control complex nonlinear systems is still an outstanding engineering challenge. In fact, despite the ubiquitous presence of large-scale nonlinear network systems, both in the technological [1] and the natural [2] fields, a full characterization of controllability has remained elusive. This is due to the fact that, in general, checking the known sufficient conditions becomes harder (intractable, even) as the size of the system increases [3]. In this letter, we address this issue by providing algebraic conditions for nonlinear control problems that leverage the system’s internal interconnection structure. Specifically, we resort to the theory of feedback linearization, which allows for the local transformation of a nonlinear system into an equivalent linear one by means of a coordinate transformation and a feedback loop [4]. This, in turn, enables the extensive array of control-theoretic tools for linear systems to be used for the control of nonlinear network systems.

While there exists a vast amount of literature on controllability of linear systems evolving on networks, the line of work studying the nonlinear counterpart is much narrower (e.g., [5], [6]). This letter complements the latter line of work and presents conditions to test whether a nonlinear network system is feedback-linearizable from a set of dedicated control inputs. Our conditions can be evaluated on the Jacobian matrix of the system computed at a desired working point, instead of complex differential geometric quantities as in classical tests, which also consist of more restrictive conditions. Finally, motivated by our interest in controlling the synchronization capabilities of neuronal networks in biological systems, we illustrate how our results can be used to achieve cluster synchronization in regular and multiplex networks of oscillatory neuronal ensembles [7], [8].

Related Work: This letter aims at narrowing the gap between controllability of large-scale network systems and the feedback linearization method. After the early theoretical developments, fewer works have surfaced on the topic of nonlinear controllability, [9], [10]. Recent papers address this problem for systems evolving on networks [5], [6], [11]–[14]. For instance, [13], [14] study accessibility of network systems. However, accessibility is a weaker notion than controllability, and thus may be of limited use in practice [15].

Feedback linearization is a classical topic in nonlinear control theory developed during the decades between the 1960 and the 1990 [16], [17]. Applications can be found in several engineering systems, including robotic mechanisms [18] and power networks [19]. Some recent work promotes the usage of data-driven methods to achieve feedback linearization whenever the model is not known exactly [20], [21]. Relevant
studies on model-based feedback linearization include [22], where the authors give conditions based on differential geometry, and [23], where conditions are given for a single-input–single-output system with delays. The work that is most closely related to ours is [19], where the authors study feedback linearization of a chain network governed by a class of nonlinear dynamics.

**Paper Contribution:** The contribution of this letter is two-fold. First, by exploiting a system’s interconnected structure, we provide sufficient algebraic conditions to test for the feedback linearization of nonlinear systems controlled by linear vector fields. That is, given a set of dedicated control inputs, we derive conditions that can be tested on the Jacobian matrix of the nonlinear system. Our conditions can be used to test for (local) controllability of large-scale nonlinear network systems. Additionally, the use of feedback linearization enables the evaluation of the state space region in which the linearized system is defined; note that this is a computation not possible when using Jacobian linearization.

Second, we exploit our results to address the challenging problem of controlling oscillatory networks [8], [24], [25]. We show that a class of nonlinearly coupled oscillators is feedback-linearizable and, through feedback linearization, we control the formation of desired synchronization patterns.

II. PROBLEM SETUP AND PRELIMINARY NOTIONS

In this letter, we study feedback linearization and controllability of nonlinear systems governed by the dynamics

$$\dot{x} = f(x) + Bu,$$

(1)

where \(x = [x_1, \ldots, x_n]^T \in \mathbb{R}^n\) is the state system, \(f\) is a smooth vector field that describes the dynamics of the system, and \(B \in \mathbb{R}^{n \times m}\) is the input matrix through which the control signals \(u\) are administered to the system. We let \(K = \{k_1, \ldots, k_m\} \subseteq \{1, \ldots, n\}\) be the control set, and let \(B = [e_{k_1}, \ldots, e_{k_m}]\), with \(e_i\) denoting the \(i\)-th canonical vector. Without loss of generality, we choose \(K \in \{1, \ldots, m\}\), and \(B = [e_1, \ldots, e_m]\). Finally, we assume that (1) has at least one equilibrium. That is, there exists \( \bar{x} \) such that \(f(\bar{x}) = 0\).

In this letter, we make use of a graphical representation of the dynamic interdependence of the system’s components. Namely, the inference diagram [26] consists of a graph \(G = (V, E)\), with \(V = \{1, \ldots, n\}\) being the set of nodes in which each node corresponds to a state of the system, and \(E \subseteq V \times V\) being the set of edges connecting the nodes as follows. For all \(i, j \in V\), there exists an unweighted directed edge from node \(j\) to node \(i\) if \(i \neq j\) and \(x_i\) appears in \(x_j\)’s differential equation. The adjacency matrix that describes the interconnection structure of the inference diagram is the sparse matrix \(A = [a_{ij}]\), with \(a_{ij} = 1\) if there is an edge between \(i\) and \(j\), and \(a_{ij} = 0\) otherwise. Fig. 1 illustrates the procedure to generate an inference diagram, which describes the underlying topology of the state interactions for the nonlinear system \(\dot{x} = f(x)\) in (1), but can equivalently represent the interconnection structure of nonlinearly interacting agents in a network system.

Let \(A\) be the adjacency matrix of \(G\), let \(\text{path}(i,j)\) denote a path on \(G\) from node \(i\) to node \(j\), and let \(|\text{path}(i,j)|\) be the number of edges of \(\text{path}(i,j)\). Notice that \(K\) represents the set of control nodes in \(G\). Define the distance between a subset of nodes \(S \subseteq V\) and the control set \(K\) as \(\text{dist}(S, K) = \min \{|\text{path}(i,j)| : i \in K, j \in S\}\). Without loss of generality, we order the nodes according to their distance from the set of control nodes. In particular, we define a positive integer \(N\) so that \(V = U_1 \cup \cdots \cup U_N\), with \(V_i \cap V_j = \emptyset\) if \(i \neq j\), and \(\text{dist}(V_i, K) = i - 1\) for all \(i \in \{1, \ldots, N\}\). According to the partition \(\{V_1, \ldots, V_N\}\), the adjacency matrix reads as

$$A = \begin{bmatrix} A_{11} & A_{12} & 0 & \cdots & 0 \\ A_{21} & A_{22} & A_{23} & \cdots & 0 \\ 0 & A_{32} & A_{33} & \cdots & \vdots \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & A_{N-1,N-1} & A_{N,N-1} \\ 0 & 0 & \cdots & 0 & A_{N,N} \end{bmatrix},$$

(2)

where \(A_{ij} \in \mathbb{R}^{|V_i| \times |V_j|}\) and \(A_{i,j-1} \in \mathbb{R}^{|V_{i-1}| \times |V_i|}\), and \(A_{i,j-1} \in \mathbb{R}^{|V_{i+1}| \times |V_i|}\), with \(|V_i|\) denoting the cardinality of \(V_i\).

In this letter, we address the following problem, whose solution is intimately tied to finding conditions for the local controllability of nonlinear systems.\(^1\) Given a nonlinear system in the form (1), we investigate whether there exists a state feedback control law \(u = \alpha(x) + \beta(x)\) and a change of coordinates \(z = \Phi(x)\) that transform the nonlinear system (1) into an equivalent controllable linear system of the form

$$\dot{z} = A_{lin}z + B_{lin}v,$$

where \(A_{lin} \in \mathbb{R}^{n \times n}\) and \(B_{lin} \in \mathbb{R}^{n \times m}\).

To answer this question, we will make use of some notions from geometric control theory [3], [27]. Given two vector fields \(f(x)\) and \(g(x)\), both defined in an open subset of \(\mathbb{R}^n\), we define the operation \([f, g]\) as the Lie bracket between \(f(x)\) and \(g(x)\), which yields the smooth vector field

$$[f, g](x) = \frac{\partial g}{\partial x}f(x) - \frac{\partial f}{\partial x}g(x).$$

To avoid confusing notation such as \([f, [f, \ldots, [f, g]]]\), we use the following recursive definition:

$$ad_f^m g(x) = [f, ad_f^{m-1} g](x),$$

where \(ad_f^m g(x) = g(x)\). Note that the directions in which the state may be moved around an initial condition are those belonging to the set of all vector fields that can be obtained by

\(^1\)A system in the form (1) is locally controllable at \(\bar{x}\) if there exists a neighborhood \(\mathcal{B}_\delta\) of \(\bar{x}\) such that for all \(x_0 \in \mathcal{B}_\delta\), there exist \(T > 0\) and a control input \(u\) that brings \(x(0) = \bar{x}\) to \(x(T) = y\).
If the function $\lambda$ is differentiable $k$ times along $f$, we write
\[ L_f^k \lambda(x) = \frac{\partial}{\partial x} \left( \frac{\partial^{k-1} \lambda(x)}{\partial x} f(x) \right). \]

For the sake of simplicity, we will omit the argument $x$ when it is clear from the context. A (smooth) distribution is the assignment of the subspace spanned by the values at $x$ of some smooth vector fields $f_1, \ldots, f_d$ that are defined in an open set $\mathcal{X} \subseteq \mathbb{R}^n$, and is denoted by $\mathcal{G} = \text{span}\{f_1, \ldots, f_d\}$. In other words, a distribution assigns a vector space to each point $x$ of the set $\mathcal{X}$. A distribution $\mathcal{G}$ is involutive if, whenever $f, g \in \mathcal{G}$, also $[f, g] \in \mathcal{G}$. Finally, the distribution $\mathcal{G}$ has constant dimension in a set $\mathcal{X} \subseteq \mathbb{R}^n$ whenever its dimension remains the same at all points in $\mathcal{X}$.

### III. Structural Conditions for Feedback Linearization

In this section, we show that if the inference diagram of a nonlinear system belongs to a well-defined class of networks, then there exists a change of coordinates such that the original controlled nonlinear system (1) can be transformed into a controllable linear system by means of a feedback law. Clearly, these conditions constitute a sufficient test for local controllability of nonlinear systems.

Before presenting our results, notice that the Jacobian $J(x) = \frac{\partial f(x)}{\partial x}$ of (1) reads as
\[
J(x) = \begin{bmatrix}
D_1(x) & U_1(x) & 0 & \cdots & 0 \\
L_1(x) & D_2(x) & U_2(x) & \cdots & 0 \\
0 & L_2(x) & \ddots & \ddots & \vdots \\
& \ddots & \ddots & \ddots & \vdots \\
0 & \cdots & \cdots & L_{N-1}(x) & U_{N-1}(x) \end{bmatrix},
\]
where the blocks have the same size of the blocks in the matrix $A$ in (2). We are now ready to present our main result.

**Theorem 1 (Condition for Feedback Linearization):** Consider the dynamics (1). Let $\tilde{x}$ be such that $f(\tilde{x}) = 0$ and let the Jacobian $J(x) = \frac{\partial f(x)}{\partial x}$ read as in (3). The system is feedback-linearizable at $\tilde{x}$ if rank($L_i(\tilde{x})$) = $|\mathcal{V}_{i+1}|$ for all $i \in \{1, \ldots, N-1\}$.

Theorem 1 implicitly requires a certain network structure to hold true, as we elucidate in the following remark.

**Remark 1 (Necessary Network Structure for the Condition in Theorem 1):** Theorem 1 requires the subdiagonal blocks of $J(\tilde{x})$ to be full row rank. Note that a necessary condition for this to hold true is that $|\mathcal{V}_{i+1}| \leq |\mathcal{V}_i|$ for all $i \in \{1, \ldots, N-1\}$ (see Fig. 2 for an example). Furthermore, every node in partition $\mathcal{V}_{i+1}$ must have at least one incoming connection from nodes in $\mathcal{V}_i$. Clearly, this interconnection requirement prevents the network topology to produce zero rows in $L_i(\tilde{x})$ for all $i \in \{1, \ldots, N-1\}$.

Before proving Theorem 1 we introduce a lemma that relates the distribution of the Lie brackets of the dynamics (1) to the image of a block triangular matrix.

**Lemma 1 (Block Upper Triangular Distribution):** Consider the dynamics (1). Let $\mathcal{G}_k = \text{span}\{\text{ad}_f^k e_{\ell} : 0 \leq \ell \leq k, 1 \leq \ell \leq m\}$, $k \in \{0, \ldots, N-1\}$. The distribution $\mathcal{G}_k(x)$ can be written as
\[
\mathcal{G}_k(x) = \text{Im}
\begin{bmatrix}
E_{1,1}(x) & \otimes & \cdots & \otimes \\
0 & E_{2,2}(x) & \cdots & \vdots \\
& \ddots & \ddots & \otimes \\
0 & \cdots & 0 & E_{k+1,k+1}(x) \\
0 & \cdots & 0 & 0
\end{bmatrix},
\]
where $\text{Im}$ denotes the image of a matrix, $G_0(x) = B$, so that $E_{1,1}(x) = I$, $E_{i,i}(x) = L_{i-1}(x)E_{i-1,i-1}(x) \in \mathbb{R}^{(\mathcal{V}_i) \times (\mathcal{V}_i)}$, $\otimes$ is any real matrix-valued function of $x$ of suitable dimension, and $0$ is a zero matrix of suitable dimension.

**Proof:** Consider first $\mathcal{G}_0(x)$, and notice that, since $\text{ad}_f^0 e_{\ell} = e_{\ell}$, for $\ell = 1, \ldots, m$, $G_0(x) = [e_1, \ldots, e_m] = B$. Next, because of the definition of $\mathcal{G}_k(x)$, at each new step $k \in \{1, \ldots, N-1\}$, $m$ new vector fields of the form
\[
\text{ad}_f^k e_{\ell} = \frac{\partial \text{ad}_f^{k-1} e_{\ell}}{\partial x} f - \frac{\partial f}{\partial x} \text{ad}_f^{k-1} e_{\ell},
\]
with $\ell = 1, \ldots, m$, add to $\{\text{ad}_f^r e_{\ell} : 0 \leq r < k, 1 \leq \ell \leq m\}$ to generate the distribution $\mathcal{G}_k(x)$. The space spanned by these new vector fields corresponds to the space spanned by the last $|\mathcal{V}_{k+1}|$ columns of $G_k(x)$, which encompass the block $E_{k+1,k+1}(x)$. In what follows we show that, because of the (block) triadiagonal structure of $A$, only the second part of (4) contributes to the definition of these columns, and, therefore, of the block $E_{k+1,k+1}(x)$. To see this, consider the Lie bracket $\text{ad}_f^k e_{\ell}(x)$ and notice that its first term reads as
\[
\left[ \frac{\partial \text{ad}_f^{k-1} e_{\ell}}{\partial x} f \right](x) = \left[ \otimes \cdots \otimes \begin{bmatrix} 0 & 0 \\ \vdots & \ddots \\ 0 & 0 \end{bmatrix} \right]^T.
\]
where \( M_1 \) is \( \tilde{n} \times \tilde{n} \), with \( \tilde{n} = \sum_{i=1}^{k} |V_i| \). Note that the definition of \( \tilde{n} \) follows from the node labeling and the fact that, for all \( j \in \{1, \ldots, N-1\} \), the nodes in \( V_j \) can only be connected with at most \( |V_{j+1}| \) nodes in \( V_{j+1} \). Thus, since the first term of each Lie bracket (4) does not affect the last \( |V_{j+1}| \) entries of the second term, the equation \( E_{j,i}(x) = L_{j-i}(x)E_{j-1,i-1}(x) \) follows by direct computation of the second term in (4), and the claimed statement follows.

In brief, the result in Lemma 1 states that each new \( \mathcal{G}_k \) “discovers” \( |V_{j+1}| \) new columns of \( G_k \) containing the entries of the block \( E_{k+1,k+1}(x) \). We use this finding to prove our main result.

**Proof Theorem 1**: For some nonnegative integer \( k \), we let \( \mathcal{G}_k = \text{span} \{a^j e_l : 0 \leq r \leq k, 1 \leq \ell \leq m \} \). The system (1) is feedback-linearizable if and only if the following three conditions hold [3, Th. 5.2.3]:

1. \( \mathcal{G}_{n-1} \) has dimension \( n \) at \( \bar{x} \);
2. for each \( 0 \leq k \leq n - 1 \), \( \mathcal{G}_k \) has constant dimension in a neighborhood of \( \bar{x} \); and
3. for each \( 0 \leq k \leq n - 2 \), \( \mathcal{G}_k \) is involutive, where \( n = |V| \). Condition 1 follows directly from Lemma 1 and from the assumption \( \text{rank}(L_{1,i}(\bar{x})) = |V_{i+1}| \) by noticing that each diagonal block \( E_{1,i}(\bar{x}) \) is full rank for all \( i \in \{1, \ldots, k+1\} \).

More in detail, let \( P \in \mathbb{R}^{m \times n_{2}} \) and \( Q \in \mathbb{R}^{m \times n_{2}} \); the fact \( \text{rank}(PQ) = \text{rank}(P) \) if \( \text{rank}(Q) = n_{2} \) implies the full rank of \( E_{1,i}(\bar{x}) = L_{1,i-1}(x)E_{1,i-1,j-1}(\bar{x}) \).

In regards to condition 2), from the assumption \( \text{rank}(L_{1,i}(\bar{x})) = |V_{i+1}| \), the continuity of singular values, and the definition of \( E_{1,i} \) in Lemma 1, it follows that the blocks \( E_{1,i}(x) \) are full row rank in a neighborhood of \( \bar{x} \). Thus, in such a neighborhood, the definition of the matrix \( G_k \) ensures that the dimension of \( \mathcal{G}_k \), for each \( 0 \leq k \leq n - 1 \), remains constant, and condition 2) holds.

Finally, to show that condition 3) holds, we observe that due to the structure of \( \mathcal{G}_k(x) \) in Lemma 1, the Lie brackets between any two vector fields in \( \mathcal{G}_k(x) \), \( 0 \leq k \leq N-1 \), cannot have nonzero rows greater than \( \tilde{n} = \sum_{i=1}^{k} |V| \). Thus, the Lie bracket \( a^j e_l \) can only contain states up to \( \tilde{n} \), and \( \mathcal{G}_k(x) \) must be involutive for all \( 0 \leq k \leq N-1 \). Note that, for \( k > N-1 \), \( \mathcal{G}_k \) clearly remains involutive. This concludes the proof.

A few comments are in order. First, Theorem 1 is constructive, can be used to check whether a network is feedback-linearizable, and also to design networks that satisfy such a property. Second, Theorem 1 implies that there exist a linearizing feedback of the form \( u = \alpha(x) + \beta(x)v \) and a diffeomorphism \( z = \Phi(x) \) that solve the space-state exact linearization problem [3, Sec. 5.2]. That is, it is possible to transform (1) into an equivalent linear system \( \dot{z} = A_{lin} z + B_{lin} v \) with \( \text{rank}(B_{lin} A_{lin} B_{lin} \ldots A_{lin}^{-1} B_{lin}) = n \). Thus, being the pair \( (A_{lin}, B_{lin}) \) controllable, Theorem 1 can also be used to assess local controllability of (1) at \( \bar{x} \).

**Corollary 1 (Condition for Nonlinear Controllability)**: Consider the dynamics (1), and let \( \bar{x} \) be such that \( f(\bar{x}) = 0 \). If the lower diagonal blocks \( L_i(\bar{x}) \), \( i \in \{1, \ldots, N-1\} \), of the Jacobian (3) have full row rank, then the system (1) is locally controllable at \( \bar{x} \).

Notice that, because the linear system \( \dot{z} = A_{lin} z + B_{lin} v \) is defined in an open set that depends on the nonlinear feedback and change of coordinates, we can evaluate the size of the region of the state space in which the linear transformation holds. In fact, if \( \Phi(x) \), \( \alpha(x) \), and \( \beta(x) \) are defined in an open neighborhood \( U \) of \( \bar{x} \), then the linear system is defined in the open set \( \Phi(U) \). This fact enables the exact characterization of the operating regions for the feedback-linearized system. Conversely, Jacobian linearization is only exact at the equilibrium point at which the Jacobian matrix is computed. It is also worth noting that Jacobian linearization does not yield the same system as the feedback-linearized one.

**Example 1 (Difference in Local Controllability Between Jacobian and Feedback Linearization)**: Consider the system (1), with \( f(x) = \left[ \begin{array}{c} x_1/2 \\ -x_2/2 \end{array} \right] \) and \( b = e_1 \). It is easy to see that the controllability matrix of the linearized system at the origin is full rank. Thus, the system is locally controllable around \( x = [0 0 0]^T \). Yet, since the distribution \( \mathcal{G}_1(x) = \text{span}(e_1, [f, e_1]) \) is not involutive, by [3, Th. 5.2.3], the system is not feedback-linearizable at \( \bar{x} \).

Is should be noted that the condition in Theorem 1 enables a general structural approach to assess feedback-linearizability of nonlinear systems with dynamics (1). Yet, it is only sufficient, as we show in the next example.

**Example 2 (Non-necessity of Theorem 1)**: Consider the system in Fig. 3 with control vector \( b = e_1 \). Notice that such a system does not satisfy Theorem 1 at \( \bar{x} = 0 \). Yet, it can be verified that the matrix \( G_2(\bar{x}) = \{ b, [f, b], [f, [f, b]] \} \) is \( \text{diag}(1, -1, 1) \), is full rank, and that \( \mathcal{G}_1 = \text{span}(b, [f, b]) = \{ 1 - 1 x_2 \} \) is involutive. Thus, by [3, Th. 5.2.3], this system is feedback linearizable at the origin.

**IV. APPLICATION TO CLUSTER SYNCHRONIZATION OF NONLINEARLY COUPLED OSCILLATORS**

In this section, we apply the results developed in Section III to the important problem of controlling the emergence of clusters of neural units with synchronized activity. Specifically, we use feedback linearization to divide networks of nonlinear oscillators into distinct synchronized clusters. We achieve this goal without resorting to the prescriptive conditions required by previous work [28], [29].

**A. Network of Kuramoto Dynamics**

Patterns of correlated activity among neural units play a role in the correct execution of cognitive functions and in the abnormal dynamics of a class of neurological disorders, such as Parkinson’s disease and epilepsy [30], [31]. A classical model used to represent the oscillatory behavior of...
brain activity is the Kuramoto model of diffusively-coupled oscillators [8], [32]. The dynamics of the \(i\)-th oscillator is

\[
\dot{\theta}_i = \omega + \sum_{j \neq i} h_{ij} \sin(\theta_j - \theta_i),
\]

where \(\omega\) represents the natural frequency of the oscillators, \(\theta_j\) is the phase of the \(i\)-th oscillator, and \(h_{ij} \in \mathbb{R}_{>0}\) denotes the coupling strength between interconnected oscillators, with \(\mathbb{R}_{>0}\) indicating the set of positive real numbers.

Interconnected systems of diffusively-coupled oscillators evolve on a network that is described by a weighted adjacency matrix \(H = [h_{ij}]\), where \(h_{ij} \in \mathbb{R}_{>0}\) if \((i, j) \in \mathcal{E}\), and \(h_{ij} = 0\) otherwise. Here, we choose the vector field

\[
f(\theta) = \begin{bmatrix}
\omega + h_{12} \sin(\theta_2 - \theta_1) \\
\omega + h_{21} \sin(\theta_1 - \theta_2) + h_{23} \sin(\theta_3 - \theta_2) \\
\omega + h_{32} \sin(\theta_2 - \theta_3)
\end{bmatrix},
\]

where \(h_{12} = h_{21} = 1\), \(h_{23} = h_{32} = 2\), and the control input is injected into the first oscillator through a control vector field \(b = [1 \ 0 \ 0]^T\). It is worth noting that for all diffusively-coupled oscillators, the inference diagram is also described by the adjacency matrix \(H\) after all weights are binarized.\(^3\)

The adjacency matrix for this illustrative example reads as \(A = [e_2, e_1 + e_3, e_2]\), and the network is depicted in Fig. 4.

With the aid of a rotating reference frame with angular velocity \(\omega\), we can study the equilibria of (5) as fixed points. We choose to stabilize the unstable equilibrium \(\bar{\theta} = \left[\pi \ \pi \ 0\right]^T\), but we remark that this network satisfies Theorem 1 at all equilibria. We start the derivation of the linearizing feedback law from the Lie brackets \(\mathrm{ad}_b\) and \(\mathrm{ad}_b^2\), which read as

\[
\mathrm{ad}_b = \begin{bmatrix}
h_{12} \cos(\theta_2 - \theta_1) & -h_{21} \cos(\theta_1 - \theta_2) & 0 \n\omega + h_{23} \sin(\theta_3 - \theta_2) & \omega + h_{32} \sin(\theta_2 - \theta_3)
\end{bmatrix},
\]

and

\[
\mathrm{ad}_b^2 = \begin{bmatrix}
h_{12}(h_{12} + h_{21} - h_{23} \sin(\theta_2 - \theta_1) \sin(\theta_3 - \theta_2)) & \star & \star \\
\star & -h_{32} h_{21} \cos(\theta_1 - \theta_2) \cos(\theta_2 - \theta_3)
\end{bmatrix},
\]

with \(\star = h_{21}(h_{12} \sin^2(\theta_2 - \theta_1) + h_{21} + 2 h_{23} \sin(\theta_1 - \theta_2) \sin(\theta_2 - \theta_1) + h_{12} \sin^2(\theta_2 - \theta_1))\). To linearize the Kuramoto network around \(\bar{\theta}\), we must compute the linearizing feedback \(u = \alpha(\theta) + \beta(0)v\), where \(\alpha(\theta)\) and \(\beta(\theta)\) can be derived from [3, Sec. 4]:

\[
\alpha(\theta) = -\frac{L^3 \Phi_1}{L_b L_n^{\phi_1}}, \quad \beta(\theta) = \frac{1}{L_b L_n^{\phi_1}},
\]

where \(\Phi_1 = L^{-1}_b \Phi_1(\theta)\), and \(\Phi_1(\theta)\) is such that

\[
\frac{\partial \Phi_1}{\partial \theta} b = 0, \quad \frac{\partial \Phi_1}{\partial \theta} \mathrm{ad} b = 0, \quad \text{and} \quad \frac{\partial \Phi_1}{\partial \theta} \mathrm{ad}^2 b \neq 0.
\]

The choice \(\Phi_1(\theta) = z_1 = \theta_1\) satisfies (6), and yields

\[
L_b L^2 \Phi_1 = h_{21} h_{32} \cos(\theta_1 - \theta_2) \cos(\theta_3 - \theta_2).
\]

From the latter, we derive \(\alpha(\theta)\) and \(\beta(\theta)\), which we omit here in the interest of space. As a proof of concept, we can easily compute the state space region where the feedback-linearized system is defined. Such a region corresponds to the open set \(\{\dot{\theta} : |\dot{\theta} - \bar{\theta}| < \frac{\pi}{2}\}\) for all \(i\), the boundary points of whose closure are the only coordinates for which \(\alpha(\theta)\) and \(\beta(\theta)\) are not defined. Finally, we can assign the poles of \(\dot{z} = A_{lin} z + B_{lin} v\) via classical static feedback \(v = -Kz\) (see Fig. 5).

**B. Multiplex Network With Multi-Body Interactions**

Multiplex networks explicitly incorporate multiple channels of connectivity in a system. In the following, we study a 2-layer multiplex network where the two layers contain neurons with three- and two-body interaction, respectively [33], [34]. Importantly, three-body interactions are thought to play a crucial role in heterosynaptic plasticity [35]. We represent neurons as oscillatory units that obey the dynamics

\[
\dot{x}_i = \omega + \kappa_1 \sum_{j=1}^{m} \sin(x_j + 2\theta_j - 2\theta_i),
\]

and

\[
\dot{\psi}_i = \omega + \kappa_2 \sum_{j=1}^{m} \sin(\psi_j - \psi_i) + d \sin(\theta_i - \psi_i),
\]

where \(\omega\) is the natural frequency, and \(\kappa_1, \kappa_2, \psi, d \in \mathbb{R}_{>0}\) are coupling strengths. We choose \(m = 3\) and we apply a control input to the \(\theta\) layer of the network (see Fig. 6(a)), so that \(B = [e_1, e_2, e_3]\). Further, we fix the constants \(\kappa_1 = \kappa_2 = d = 1\). By writing the state of the network as \(x = [\theta_1 \ 2\theta_2 \ 3\theta_3 \ \psi_1 \ \psi_2 \ \psi_3]^T\), it can be shown that \(\dot{x} = [\pi \ \pi \ 0 \ 0 \ 0 \ 0]^T\) is an unstable equilibrium point of (7). It holds that \(J(\bar{x}) = 1 - 4 \mathrm{diag}(-d, -d, -d, -d, -d, -d)\).

Hence, the condition in Theorem 1 is satisfied and the system is feedback-linearizable at \(\bar{x}\). Along the lines of [3,
whereas the θ layer consists of neurons connected with two-body interactions, whereas the ϕ layer consists of neurons connected with three-body interactions. (b) The convergence of the system’s state to the desired point after feedback linearization. The eigenvalues of $A_{lin} + B_{lin}K$ are assigned to the left half plane, thus making $\dot{x} = [\pi \pi \pi 0 0 0]^T$ locally stable in the reference frame rotating with velocity $\omega$.

Proof of Lemma 5.2.2], we compute the dummy output functions $\lambda_1(x) = \phi_1$, $\lambda_2(x) = \phi_2$, and $\lambda_3(x) = \phi_3$, from which we obtain the local change of coordinates $\phi_i(x') = I_{k-1}^{-1}\lambda_i(x)$, $1 \leq k \leq 2$, $1 \leq i \leq 3$, and finally the linearizing feedback law [3, Sec. 5]. The code for this simulation can be downloaded at [36]. In Fig. 6(b), the computed feedback partitions the network into two distinct clusters. This result extends existing work on the control of cluster synchronization in networks of nonlinearly-interacting oscillators (see, e.g., [8]) to more complex types of interactions.

V. CONCLUSION AND FUTURE DIRECTIONS

We have derived sufficient structural conditions to test for feedback-linearizability of large-scale nonlinear network systems. These conditions also constitute a test for local controllability. The results contained in this letter are particularly suited for large networks, such as multi-agent systems, neuronal networks, and artificial neural networks.

Because of striking topological similarities, future research could investigate the link between feedback-linearizable and strongly structurally controllable networks [37]. Finally, another interesting research direction is the characterization of the gap between locally controllable and feedback-linearizable systems [38].
